

3D Marker Tracking Cameras on Low-Cost Embedded Platforms

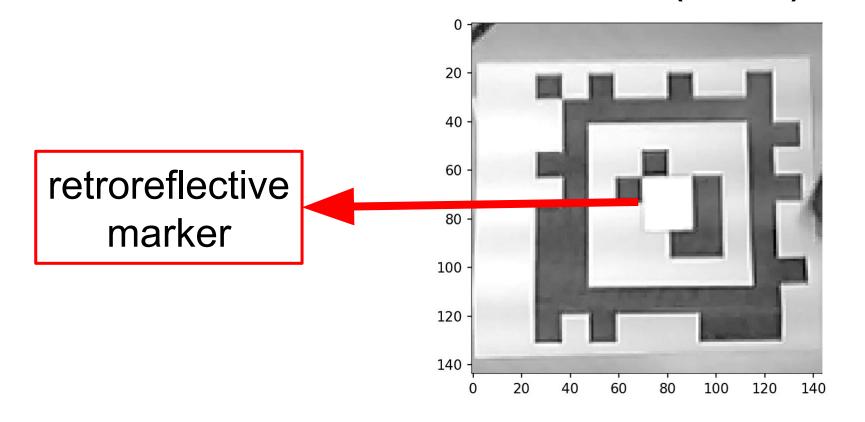

EECS 452: Digital Signal Processing Design Lab – Winter 2024 Vishal Chandra, Darren Fitzgerald, Sonia Kim, Aida Ruan, Andrew Schallwig

Motivation

The core goal of our project is to implement a low-cost embedded motion capture system that can accurately localize and track points in space, while running efficiently on easily-accessible hardware. This technology allows small game studios, independent filmmakers, and researchers to effectively localize points on objects at low cost.

Methods

- Image Processing
 - Detect retroreflective marker
 - Detection aggregation
- Windowing
- Wireless Communication
- UDP packets
 - Windowed image
 - Timestamp
 - Camera ID
- 3D Marker Localization
- April Tag Detection (48h12 custom tag family with no center)
- Extended Kalman Filter (EKF)

Windowed Tag Detection

Challenges

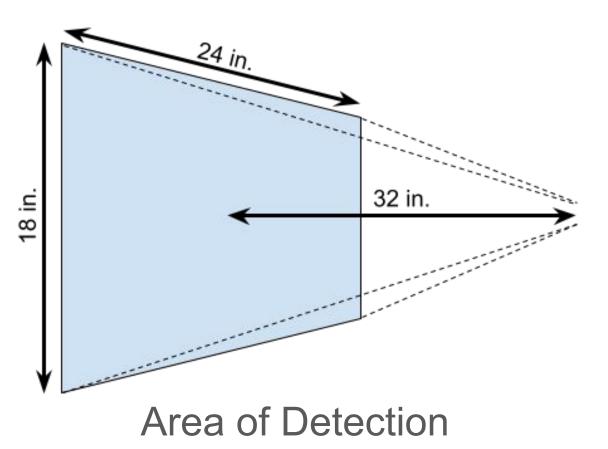

- Accuracy of marker identification
- Camera Extrinsics
- Intermittent marker visibility through time
- Computational constraints of the ESP32-Cam

System Architecture **Base Station Processor** Identifiable match camera Markers observations by Preprocess marker + convert to Image Data Capture 2D locations purely numerical data of markers at each camera view Extended iterative reconstruction -Kalman Filter ESP32-Cams predict & update reduce px touched Reconstruct skip every 4 px projections into point Decimate cloud rows/cols Localize threshold Retroreflectors retroreflected points visualize 3D points Rust Simulation Capture reflector capture tags assoc. interface neighborhood w/ each reflector (marker) Transmit data over UDP Tested with synthetic UDP data packets containing: (x,y) marker coordinates, marker AprilTag ID, cam ID Stabilizes cameras Mount w.r.t each other In complete system we know camera intrinsics and calibration extrinsics which are used for filtering Reconstruction Algorithm Reconstructed 3D point cloud, latest point in blue **Parallel Filters** Marker 1 EKF Marker 2 EKF Camera 2 Marker 3 EKF ESP32-Cam and **EKF Filter Bank** Reconstructed Points Experimental Diagram

- I. Label measurement with marker ID according to April Tag detection
- 2. Initialize state vector (center point of the marker in 2D), covariance matrix, measurement noise covariance matrix
- 3. Linearize state measurement model for the given camera
- 4. Update state and covariance using the Kalman gain and difference between measurement of currently predicted state and new measurement
- 5. Iterate step 4 for measurements across cameras and time

Results

We found that our 3D marker tracking system is constrained by memory and processing speeds of the ESP32-Cam. This limited our image resolution and thus the area of detection.

Without JPEG encoding, the ESP32-CAM only supports up to VGA (320x240). Accessing the image buffer within PSRAM is also slower than SRAM. Additionally, we experimented with sending the image over serial, but it was much slower than UDP.

	# Tags	Average Frame Rate
	1	100 FPS
	2	70 FPS
	3	50 FPS

Detection and Transmission
Performance under Variable Load

We compared performance and accuracy of EKF versus UKF. Because EKF uses analytic linearization, it is faster. However, we expect UKF to be more accurate on the synthetic data.
